Silensis Tool Software

A General description

What do we need to ensure compliance with the acoustic insulation requirements on site established by the DB HR?

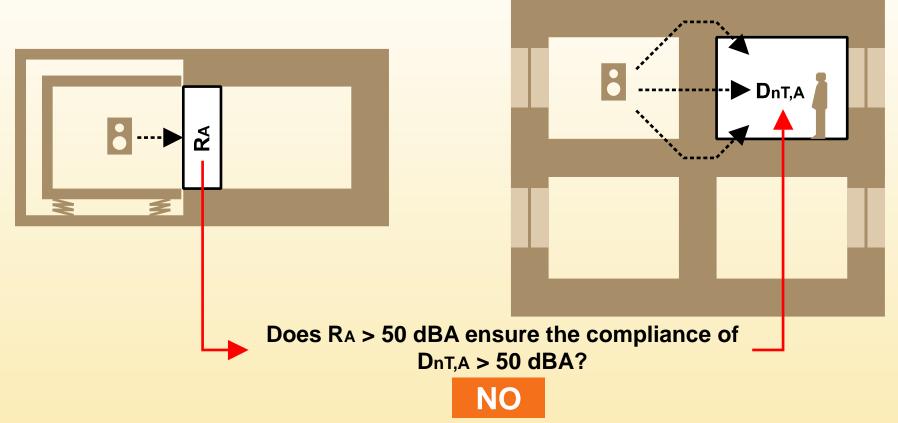

Good acoustic insulation of the constructive elements in the laboratory

Proper combination of the constructive elements

Proper design of the unions between constructive elements

Correct execution on site

The airborne sound insulation on site depends on other factors:

Geometry of the enclosures

Acoustic performance of the elements

Design of the unions between elements

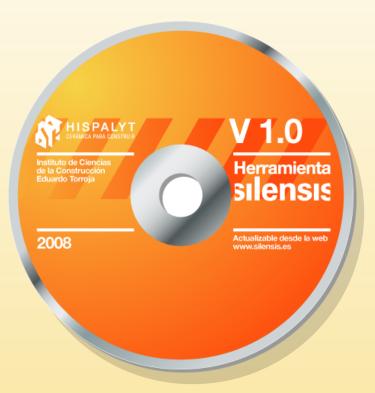

Correct execution

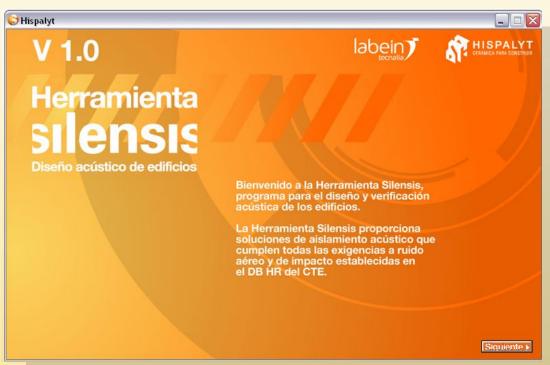

A good sound insulation of the separating wall measured in laboratory is necessary but is not sufficient to comply with the on site requirements of the CTE

SILENSIS Tool

For the acoustic design of the building employing ceramic solutions

Software for the acoustic design and verification of the "Ceramic solutions Catalogue for compliance with the CTE".

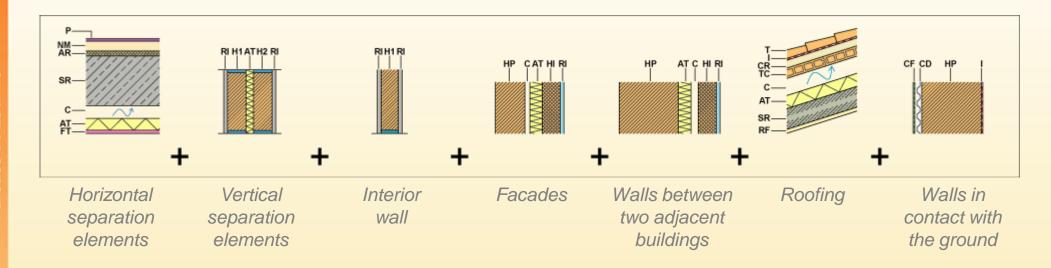

SILENSIS Tool

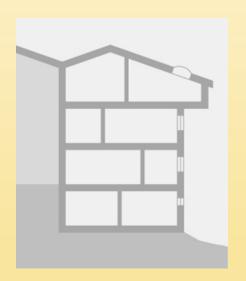

What does the Silensis Tool give us?

Using SILENSIS partition walls.....

	Party walls to complian	ce the DB HR of the CT	E	
Single wall	Double wall		Triple wall	
Silensis Type 1A	Silensis Type 2A	Silensis Type 2B	Silensis Type 1B	
Single wall composed by a hea∨y wall without elastic bands	Double wall composed by 2 lightweight walls with perimetral elastic bands and absorbent material in the air chamber	Double wall composed by 1 hea∨y wall supported and 1 lightweight wall with perimetral elastic bands and absorbent material in the air chamber	Triple wall composed by 1 heavy wall supported and 2 lightweight walls with perimetral elastic bands in both sides and absorbent material in the air chambers	
Type 1 of the CTE DB HR	Type 2 of the CTE DB HR	Type 2 of the CTE DB HR	Type 1 or 2 of the CTE DB HR	
	SILENSIS S	OLUTIONS		

What does the Silensis Tool give us?

The Silensis Toolprovides

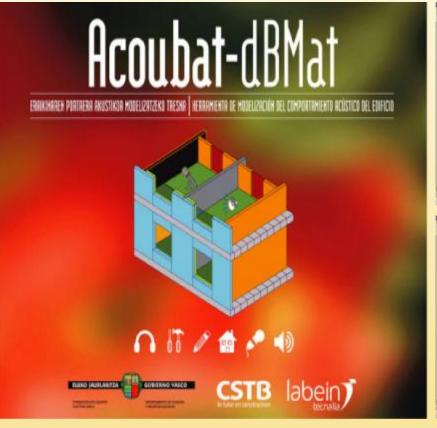

Acoustic insulation solutions

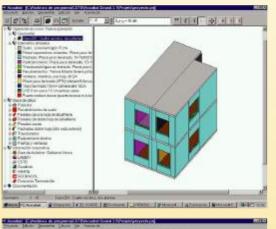

Combinations of all the constructive elements of the building, meeting the requirements of sound insulation to exterior noise and interior noise (airborne and impact) established by the CTE DB HR.

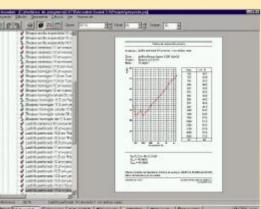

How does the Silensis Tool software work?

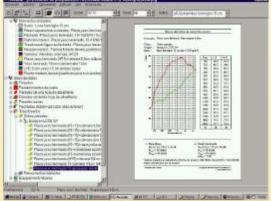

Predictive calculations of the Silensis Tool software

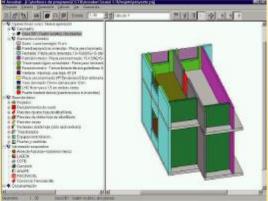

- ❖ Acoustic Solutions validated by the Acoubat dBMat developed by Labein for the Basque Government (based on the engineering model of the UNE EN 12354)
- Predictive studies using laboratory tests of different constructive elements.

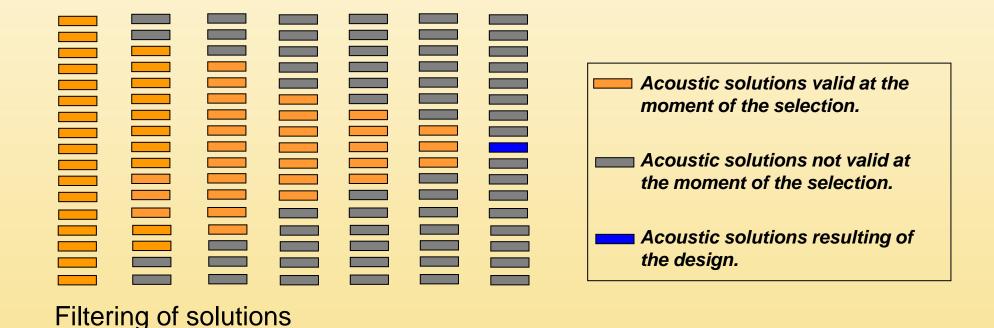

0.4 Design tools about Silensis developed by Hispalyt04.2-A Silensis Software for the acoustic design of buildings. General description

How does the Silensis Tool software work?

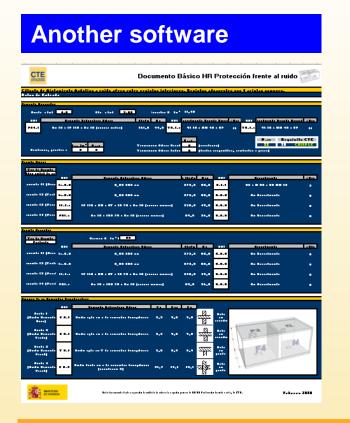

Acoustic insulation solutions

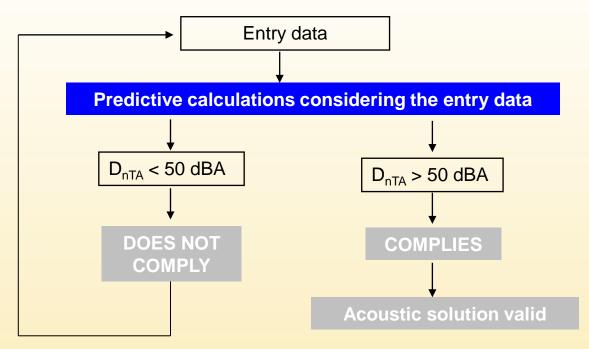

- ❖ The Silensis Tool software is not a software with a calculation engine inside.
- ❖ The Silensis Tool software has many already made calculations of acoustic insulation solutions, combinations of constructive elements (facade, partitions, interior walls, etc...) that comply, in the worst geometry conditions, with the requirements of sound insulation to exterior noise and interior noise (airborne and impact) established by the CTE DB HR.
- ❖ At the same time that the user selects and introduces data, the software Silensis Tool filters the valid solutions.

Progress in the acoustic design of the building

Software Silensis Tool

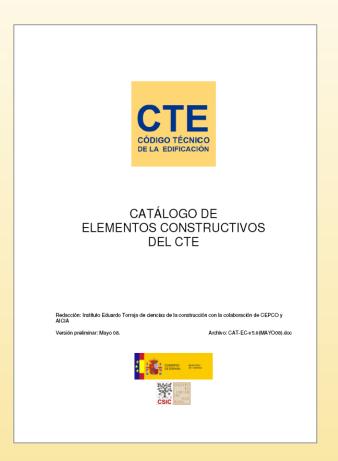

How does the Silensis Tool software work?

Database of construction components of the Silensis software

Ceramic elements

(Facades, partition walls, interior wall, etc.)

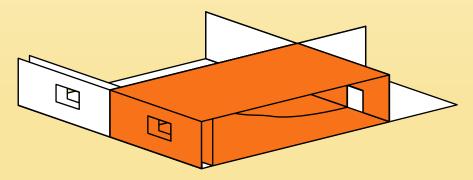

Non ceramic elements
(floor structures, floating floor, windows)

How does the Silensis Tool software work?

Database of construction components of the Silensis software

What parameters characterize the acoustic performance of the constructive elements?

Facade of one wall	m (kg/m²) y R _A (dBA)
Facade of two walls. Interior wall	m (kg/m²) y R _A (dBA)
Roof	m (kg/m²) y R _A (dBA)
Walls between two adjacent buildings	m (kg/m²) y R _A (dBA)
Walls in contact with the ground	m (kg/m²) y R _A (dBA)
Floor structure in contact with the exterior air	m (kg/m²) y R _A (dBA)
Party walls between enclosures	m (kg/m²) y R _A (dBA)
Interior wall	m (kg/m²) y R _A (dBA)
Floor structure	m (kg/m 2), R $_A$ (dBA) y L $_{NW}$ (dB)
Floating floor	ΔL_W (dB) y ΔR_A (dBA)
False ceilings	ΔL_W (dB) y ΔR_A (dBA)

Acoustic design of the building

Acoustic requirements for protection	Acoustic design	Constructive elements	Enclosures considered

		10 Interior wall					

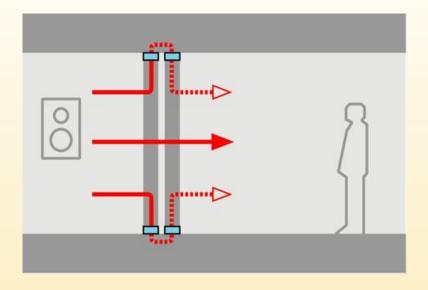

- ❖ The selection of the constructive elements is done in a sequential mode.
- ❖ It is only allowed to use constructive elements which combined with the other elements previously selected by the user, comply with the acoustic requirements.

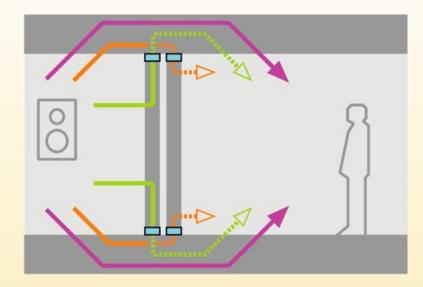

The program distinguishes between different types of buildings

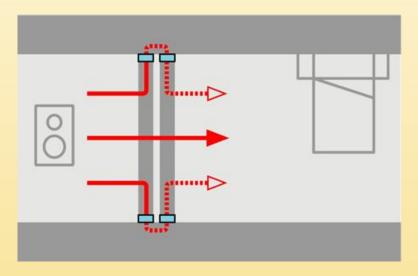

❖Four types of buildings have been identified aiming to adapt to the requirements in each case.

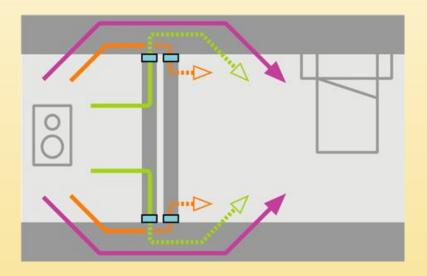

The program considers differents union types

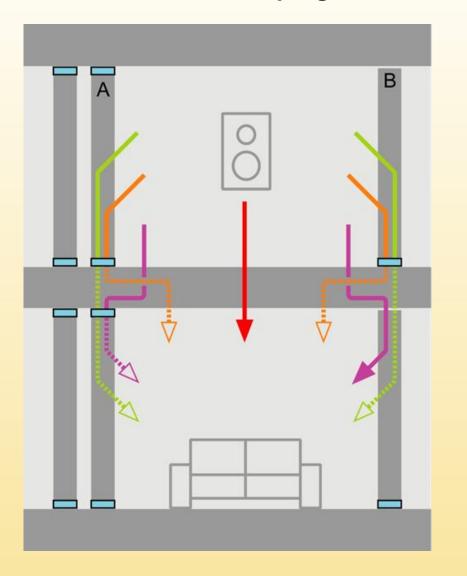

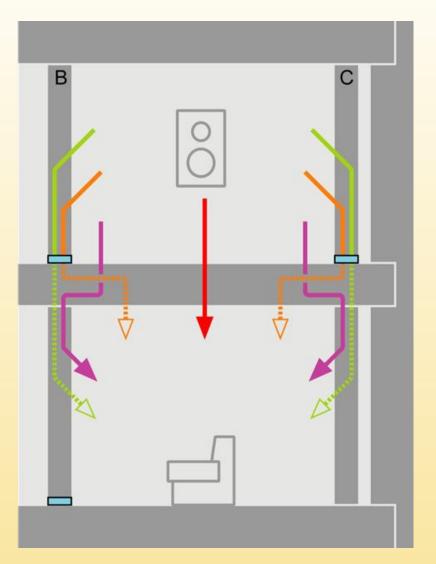

The ELASTIC BANDS PERIMETER in the double walls partitions (****) improves sound insulation to airborne noise in horizontal due to disruption of structural acoustic bridge (****) and certain indirect transmission paths (****).

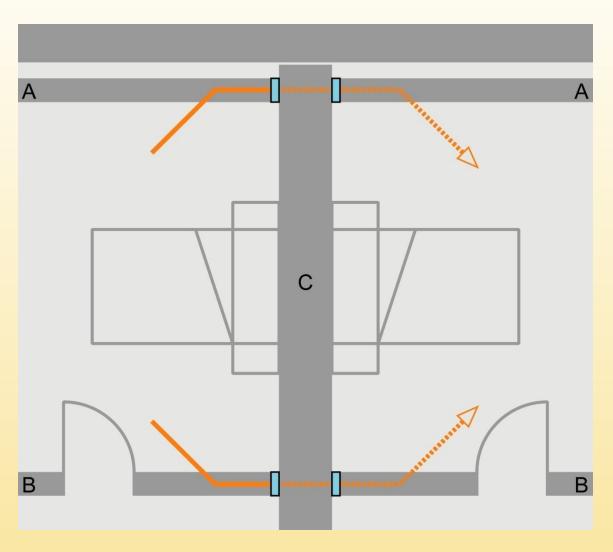

The program considers differents union types

The ELASTIC BANDS IN THE BASE () of partition walls (A), interior walls (B) and inner wall of the facade (C) improves acoustic insulation to airborne noise in vertical, by disrupting certain indirect transmission paths ().

The program considers differents union types

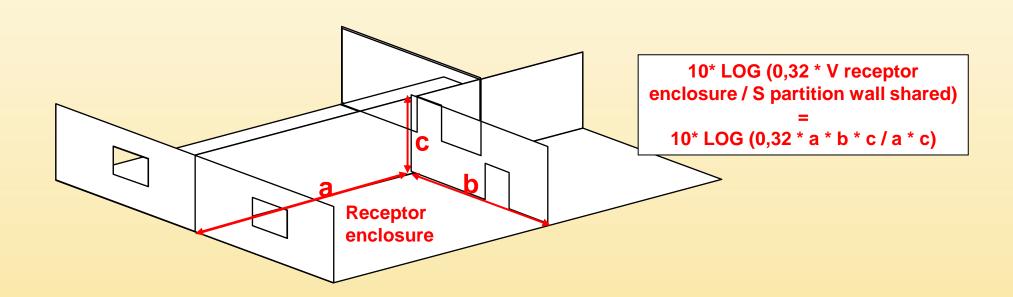

The ELASTIC BANDS IN VERTICAL at the union of the interior walls (B) and inner walls of the facade (A) with the simple partition walls (C), interrupts transmission paths "interior wall-interior wall" (B) and "inner wall of the facade-inner wall of the facade" (a), which in some cases could be critic, improving the sound insulation to airborne noise in horizontal.

0.4 Design tools about Silensis developed by Hispalyt04.2-A Silensis Software for the acoustic design of buildings. General description

The Silensis program considers different geometries

❖ The sound insulation between rooms depends on the geometry of the enclosures.

Geometry factor:
10* LOG (0,32 * V receptor enclosure/ S partition wall shared)

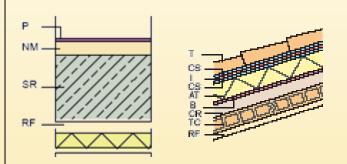

❖ In order to optimize the solutions, many calculations have been carried out considering different relations (V receptor enclosure / S partition wall shared):

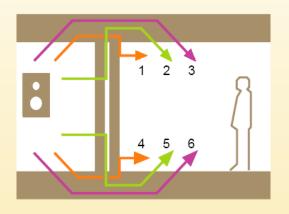

The Silensis program distinguishes between: Enclosure of intermediate storeys / Enclosure of storeys under roof

Floor structure in intermediate storeys / Floor structure in storeys under cover

Different indirect transmissions

Different types of partition walls

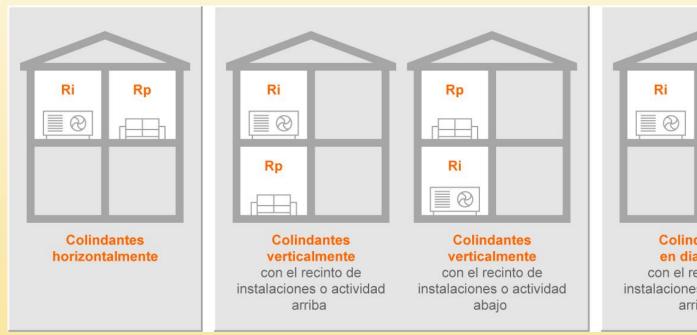

Different types of floor and ceiling coverings

0.4 Design tools about Silensis developed by Hispalyt04.2-A Silensis Software for the acoustic design of buildings. General description

The Silensis program contemplates different configurations of facility enclosures and activity enclosures

- We have considered various configurations between facility enclosures or activity enclosures, and the dwelling enclosures, depending on the requirements in each case:
 - Horizontally adjacent enclosures: with sound insulation requirement horizontally
 - Vertically adjacent enclosures: with sound insulation requirement vertically
 - Diagonally adjacent enclosures: with sound insulation requirement diagonally

SILENSIS TOOL Report

The Silensis Tool

SILENSIS TOOL Report

❖ Detailed description of the selection of constructive elements made in the acoustic design.

La fachada es del tipo:

Hoja principal de 1/2 pie con revestimiento discontinuo, cámara ventilada por el interior, aislante térmico por el interior.

El subtipo de fachada viene determinado por los siguientes componentes:

La fachada debe cumplir unos valores de masa y aislamiento acústico de:

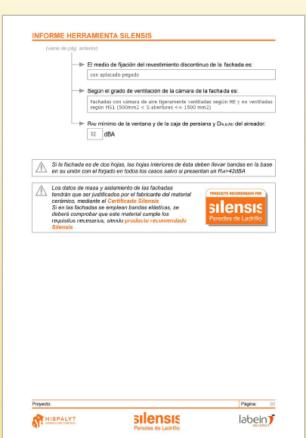

La hoja principal de la fachada de doble hoja debe cumplir:

0.4 Design tools about Silensis developed by Hispalyt04.2-A Silensis Software for the acoustic design of buildings. General description

The Silensis Tool

SILENSIS TOOL Report

- Definition of the union type between constructive elements
- ❖References:
 - "Silensis Recommended Products" of elastic bands and absorbing materials.
 - "Certificate Silensis" of the ceramic products of the manufacturers.

Si la fachada es de dos hojas, las hojas interiores de ésta deben llevar bandas en la base en su unión con el forjado en todos los casos salvo si presentan un RA>42dBA

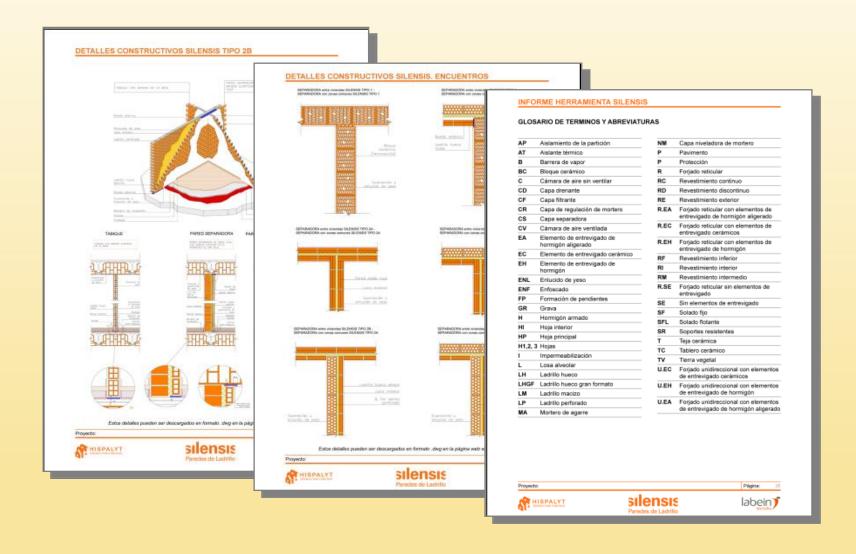

Los datos de masa y aislamiento de las fachadas tendrán que ser justificados por el fabricante del material cerámico, mediante el Certificado Silensis Si en las fachadas se emplean bandas elásticas, se deberá comprobar que este material cumple los requisitos necesarios, siendo producto recomendado Silensis
